Introduction

This report uses logistic regression to determine the log odds relationship between the presence of government responses to covid-19 and the presence of cases of the virus.

Import dataset.

In [121…
```
df=Json('df1: government responses to covid19')
df.excel('Gov_Responses2Covid19_last.xlsx', 'Dataset')
df1=json_storage['df1: government responses to covid19'][1]
df1
```

62700 rows × 21 columns

The model will be determining whether cases of the virus were present. Makes all values where cases were above 0 into 1.

In [127…

```
df1['cases']=df1['cases'][df1['cases'] > 0] = 1
```

Data Exploration

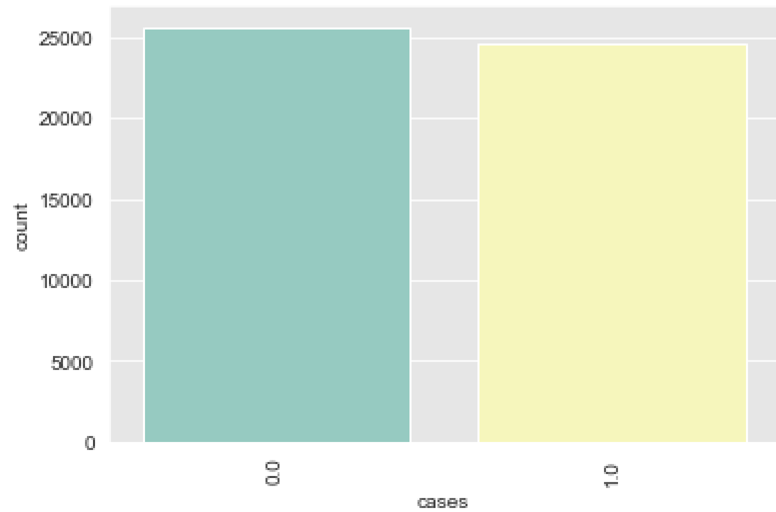
There is no class imbalance.

In [128…

```
sns.countplot(y_train, palette='Set3')
plt.xticks(rotation=90)
```

Out[128…

```
(array([0, 1]), [Text(0, 0, '0.0'), Text(1, 0, '1.0')])
```



Government Regulation Features

The Governments' responses to COVID19 are the measures implemented by governments worldwide in response to the Coronavirus pandemic. There are two types of measures: public health measures and economic measures. .
The variables are :

- cases: binary variable equal to 1 if there were cases of SARS-CoV-2 and 0 otherwise;
- school: binary variable equal to 1 if schools were closed and 0 otherwise;
- domestic: binary variable equal to 1 if there was a domestic lockdown and 0 otherwise;
- travel: binary variable equal to 1 if travel restrictions were implemented and 0 otherwise;
- travel_dom: binary variable equal to 1 if travel restrictions within the country (e.g. inter-region travels) were implemented and 0 otherwise;
- curf: binary variable equal to 1 if a curfew was implemented and 0 otherwise;
- mass: binary variable equal to 1 if bans on mass gatherings were implemented and 0 otherwise;
- elect: binary variable equal to 1 if some elections were postponed and 0 otherwise;
- sport: binary variable equal to 1 if bans on sporting and large events were implemented and 0 otherwise;
- rest: binary variable equal to 1 if restaurants were closed and 0 otherwise;
- testing: binary variable equal to 1 if there was a public testing policy and 0 otherwise;
- surveillance: binary variable equal to 1 if mobile app or bracelet surveillance was implemented and 0 otherwise;
- masks binary variable equal to 1 if the obligations to wear masks in public spaces was implemented and 0 otherwise;
- state: binary variable equal to 1 if the state of emergency is declared and 0 otherwise;
- cash: binary variable equal to 1 if cash transfers are implemented and 0 otherwise;
- wage: binary variable equal to 1 if wage support is implemented and 0 otherwise;
- credit: binary variable equal to 1 if credit schemes are implemented and 0 otherwise;
- taxc: binary variable equal to 1 if tax credits are implemented and 0 otherwise;
- taxd: binary variable equal to 1 if tax delays are implemented and 0 otherwise;
- export: binary variable equal to 1 if supports to importers or exporters are implemented and 0 otherwise;
- rate: binary variable equal to 1 if the Central Bank lowered the interest rates and 0 otherwise;

Feature Engineering

Makes the dependent variable y be the cases and the independent variables X be the government regulations. Then, splits data, 80/20, into a train test split.

In [129…
```
y=df1[('cases')]
X=df1.drop(['cases'], axis=1)

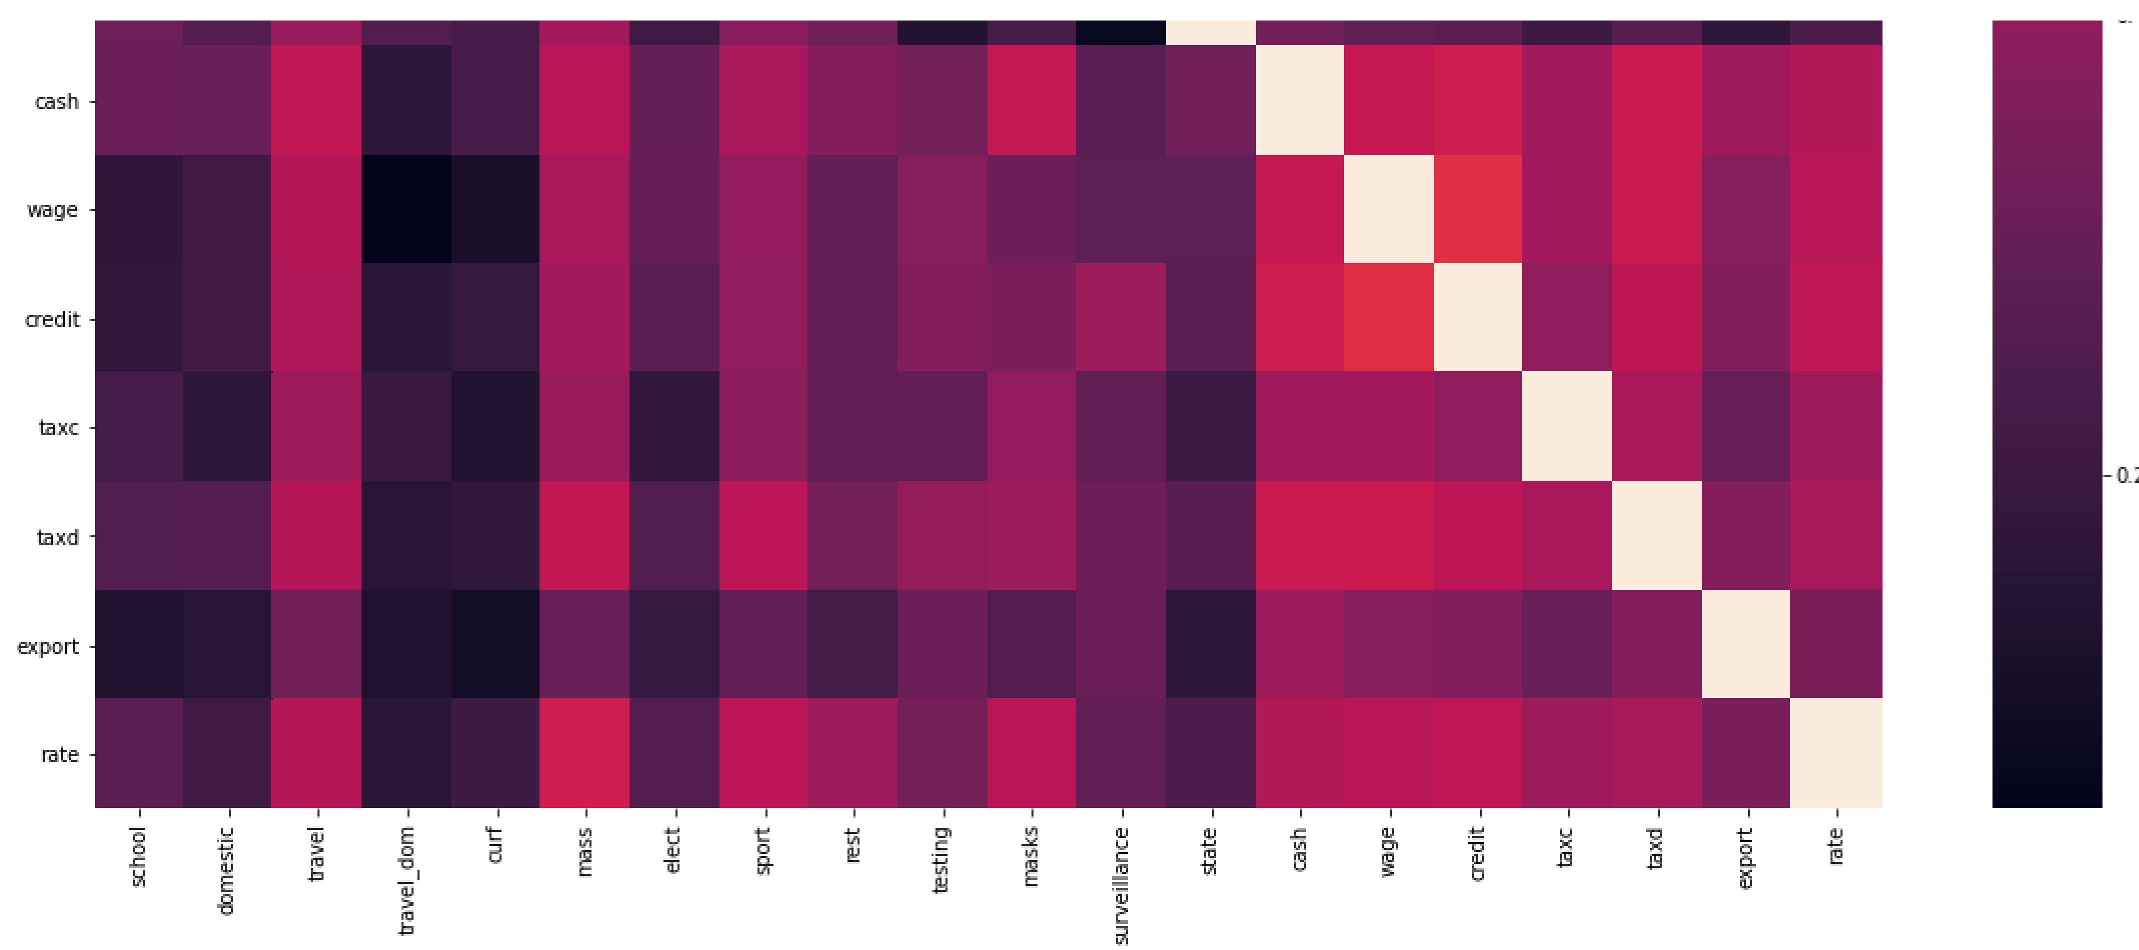
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)
```

Binary logistic regression assumsions are a binary dependent variable, independent observations, linear continuous variables, no strongly influential outliers, independent variables with no multicollinearity, and and a large sample size. The dependent variable is zero or one, the observations are not repeated measurements made on each experimental unit or matched -- when pairs of data are matched based on similar features, there are no continuous variables, the data are zeros and ones so there are no outliers, and the data has 50160 rows.

Check for muticollinearity.

In [25]:
```
x_corr=X_train.corr(method='pearson')
plt.figure(figsize=[20, 20])
sns.heatmap(x_corr)
```

Out[25]: <AxesSubplot:>



In [26]:
```
correlation=[]
for columnName1, columnData1 in X_train.iteritems():
    for columnName2, columnData2 in X_train.iteritems():
        if abs(columnData1.corr(columnData2)) > .7:
            correlation.append((columnName1, columnName2, abs(columnData1.corr(columnData2))))
correlation
```

Out[26]:
```
[('school', 'school', 1.0),

Remove multicollinear feature from X.

In [ ]:
```
X_train=X_train.drop('sport', axis=1)
X_test=X_test.drop('sport', axis=1)
```

Logistic Regression Model

The Logistic function, logit(P), starts with setting the log odds equal to the parameters. Exponentiate both sides of the equation and cross multiply 1-P to get the logistic function.

$$ln(\frac{P}{1-P}) = \alpha + \beta x$$

$$\frac{P}{1-P} = e^{\alpha+\beta x}$$

$$P = \frac{e^{\alpha+\beta x}}{1+e^{\alpha+\beta x}}$$

The probability of class 1 is the logistic function and of class 0 is one minus the logistic function.

$$P(Class = 1|X = x) = \frac{e^{\alpha+\beta x}}{1+e^{\alpha+\beta x}}$$

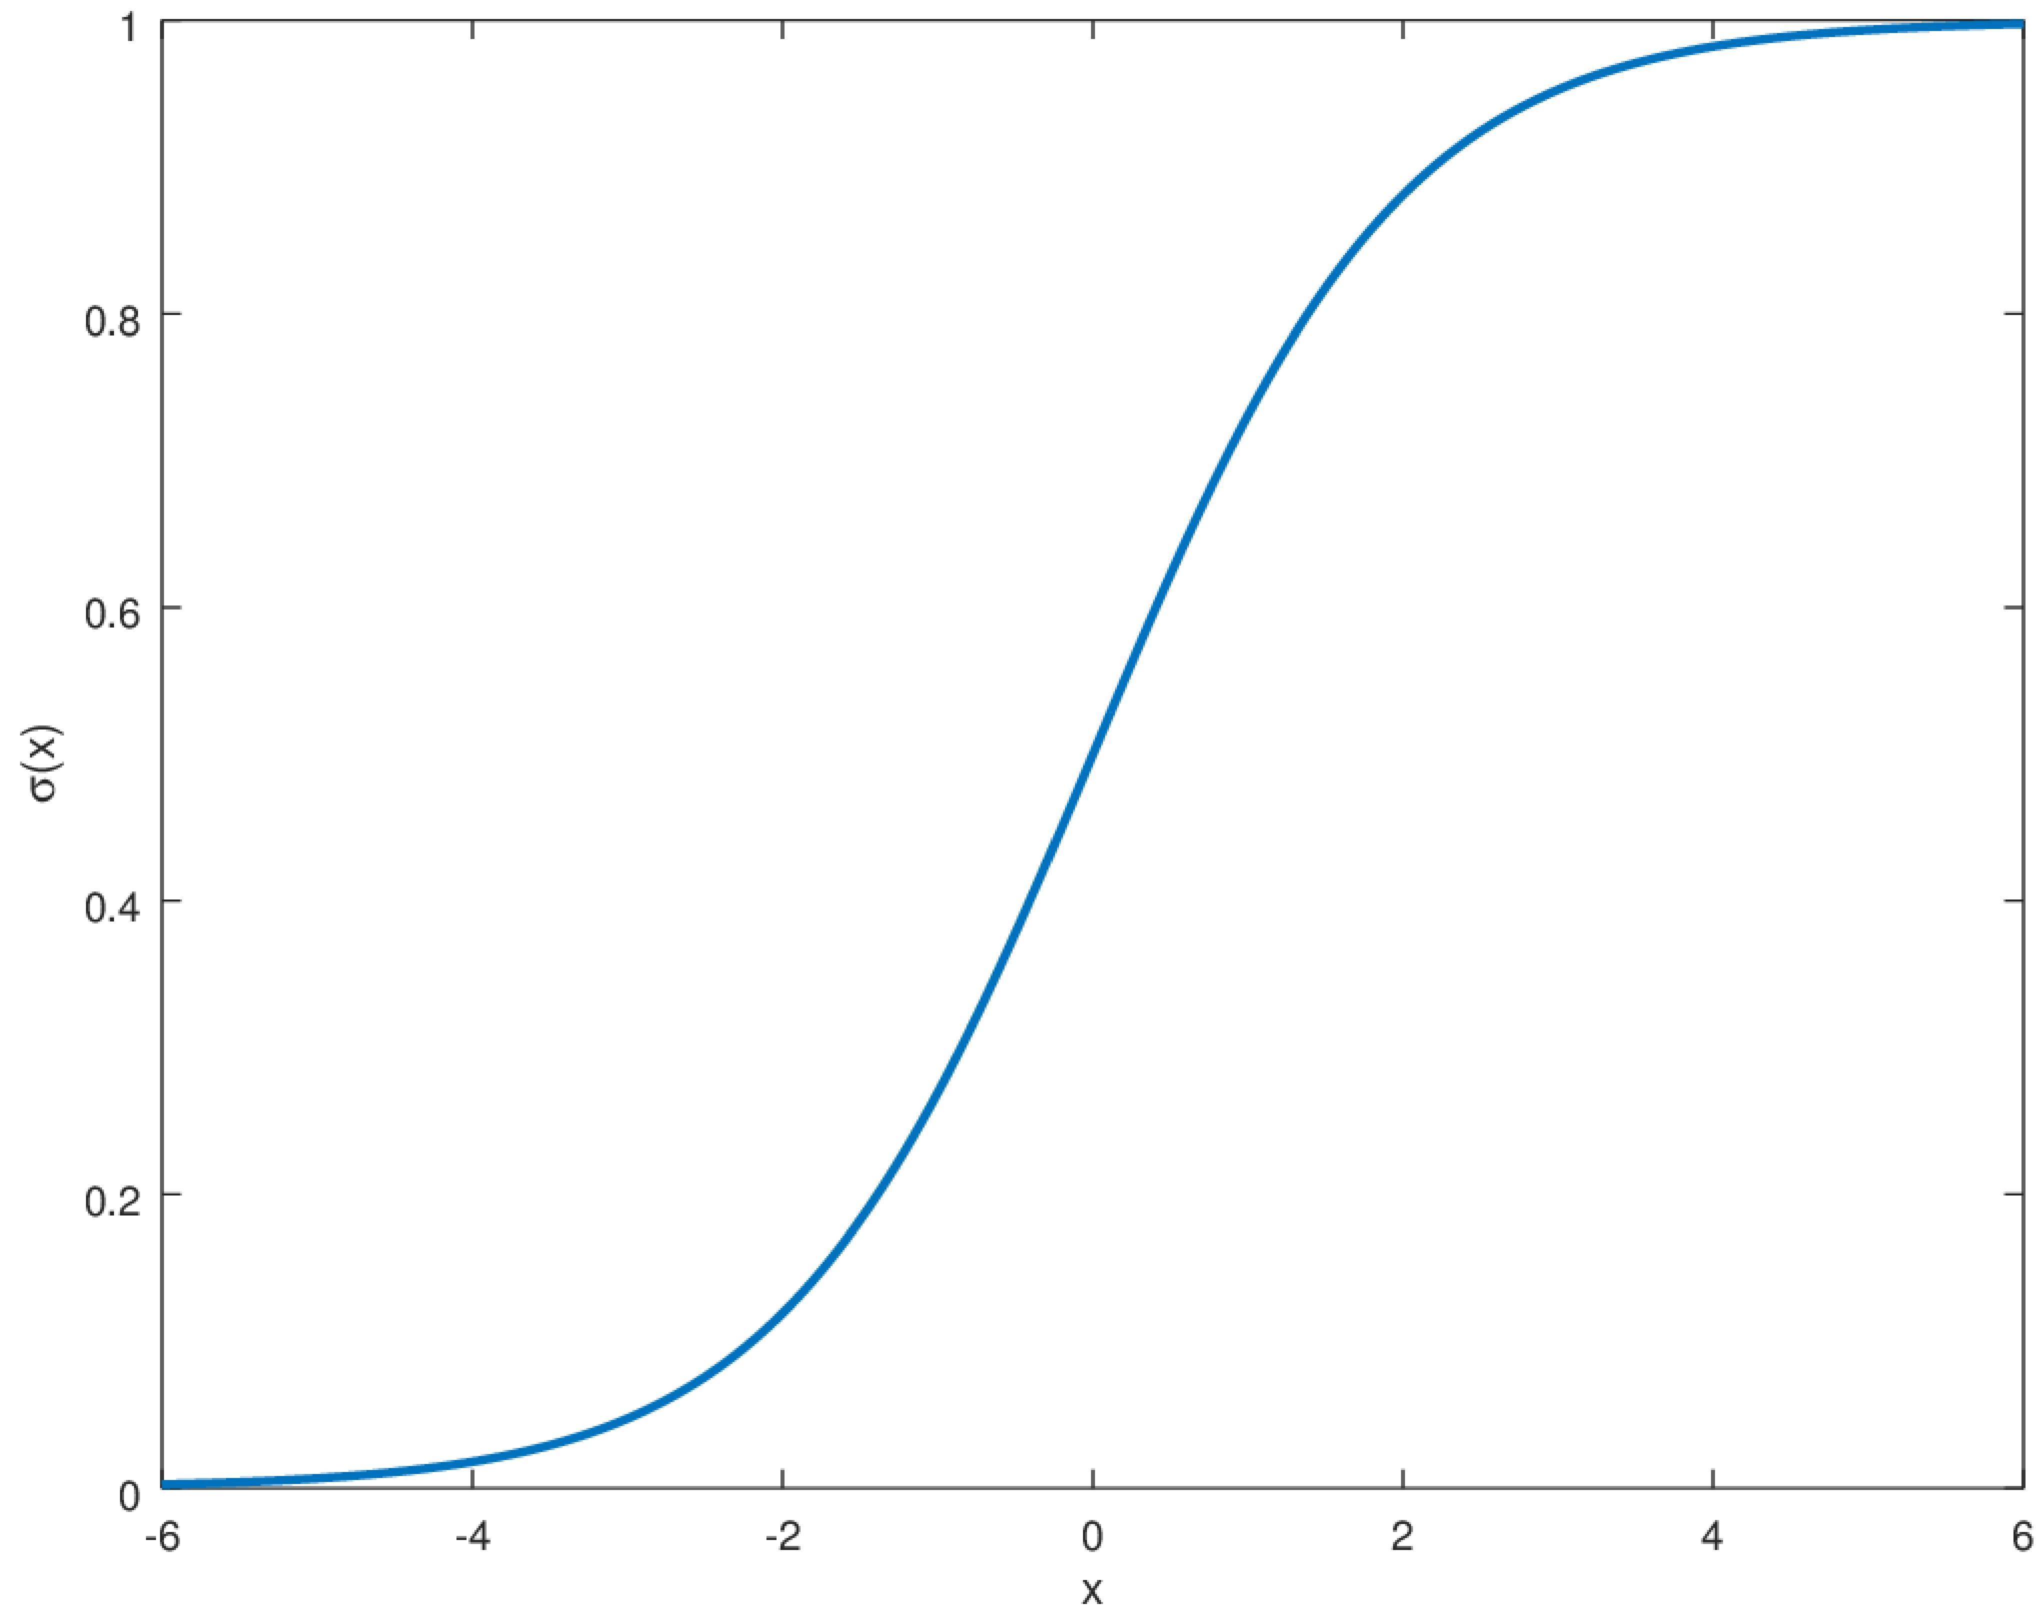
$$P(Class = 0|X = x) = 1 - \frac{e^{\alpha+\beta x}}{1+e^{\alpha+\beta x}}$$

Take the inverse of P to get the desired sigmoid function.

$$\sigma(x) = P^{-1} = \frac{1}{1+e^{-(\alpha+\beta x)}}$$

In [27]:
```
Image(filename='sigmoid_function.png')
```

Out[27]:

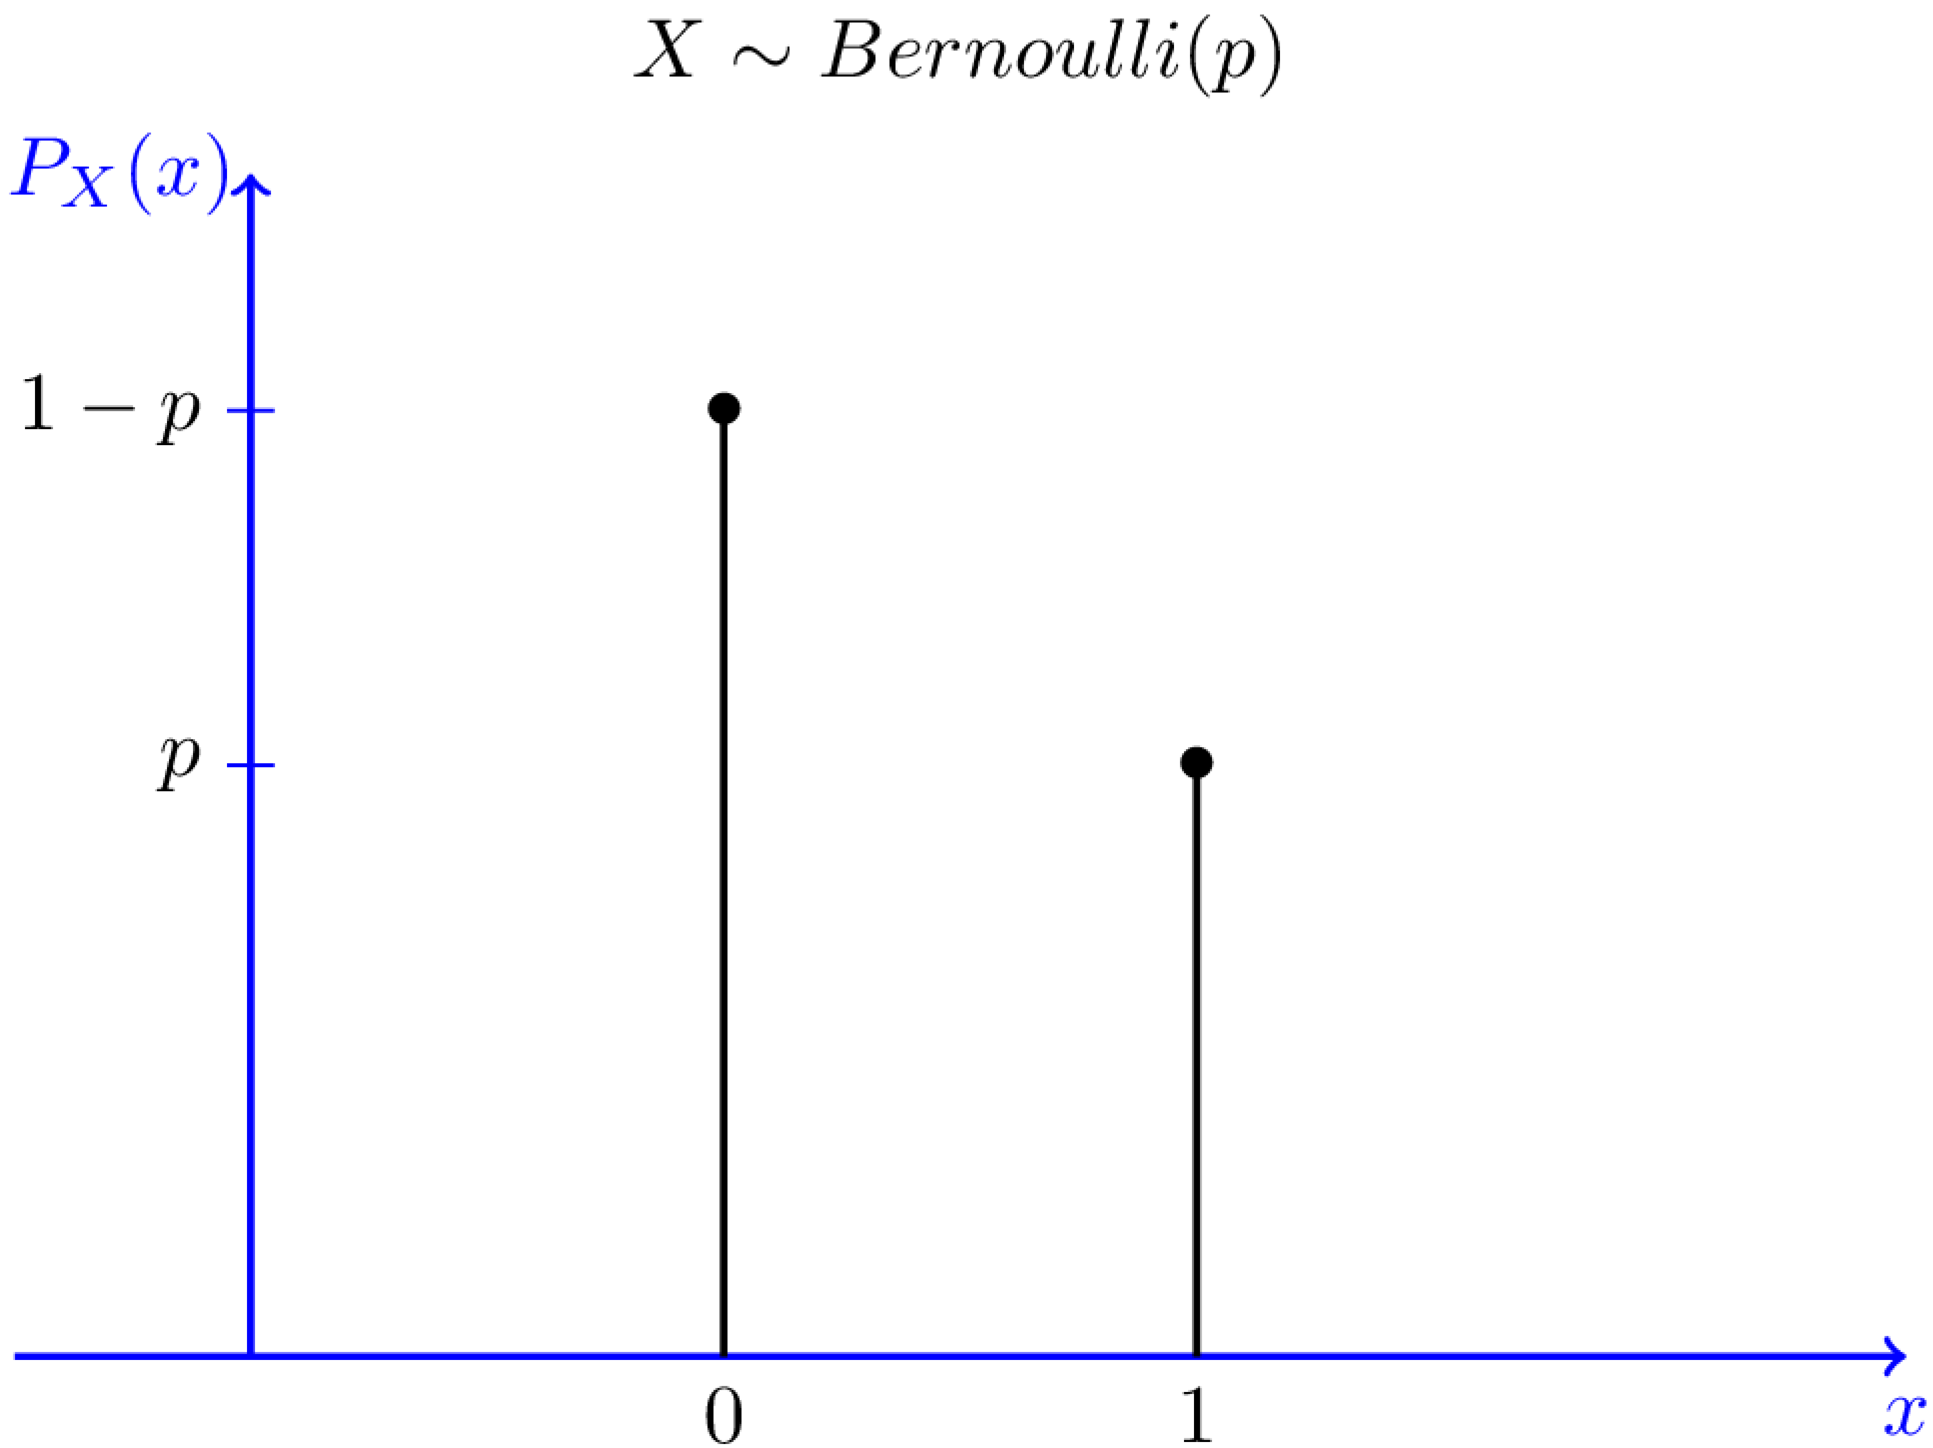


The predicted labels are binary so each label is a Bernoulli random variable from a Bernoulli probability mass function.

$$P(x;p) = \begin{cases} p & : x = 1 \\ 1-p & : x = 0 \end{cases}$$

In [28]:
```
Image(filename='bernoulli(p) color.png')
```

Out[28]:



MLE, maximum likelihood estimation, finds the parameters, θ, that maximize the log likelihood probability, a model comparitive metric, that a value belongs to a class.

$$MLE = \prod_i^N P(Y = y_i | X = x_i)$$

$$argmaxLL(\theta) = \sum_i^N y_i * log(\sigma(\theta^T * x_i)) + (1 - y_i) * log(1 - \sigma(\theta^T * x_i))$$

Solve for θ that maximizes the the log likelihood by solving for the partial derivative of the log likelihood with respect to θ and gradiently accend toward the maximum of the LL function.

$$\nabla \frac{\partial LL(\theta)}{\partial \theta_j} = \sum_i^N [y_i - \theta^T * x_i] x_{ij}$$

Iteratively accend toward maximum LL with an η stepsize.

$$\theta_j^{new} = \theta_j^{previous} + \eta * \nabla \frac{\partial LL(\theta^{previous})}{\partial \theta_j^{previous}}$$

The McFadden R squared, a model comparitive metric, is 1 minus the log likelihood of the full model, which is like the sum of squared residuals, devided by the log likelihood of the intercept model, which is like the total sum of squares.

$$R^2_{McF} = 1 - \frac{lnL(M_{full})}{lnL(M_{int})}$$

Conduct logistic regression model from statsmodels for regression results.

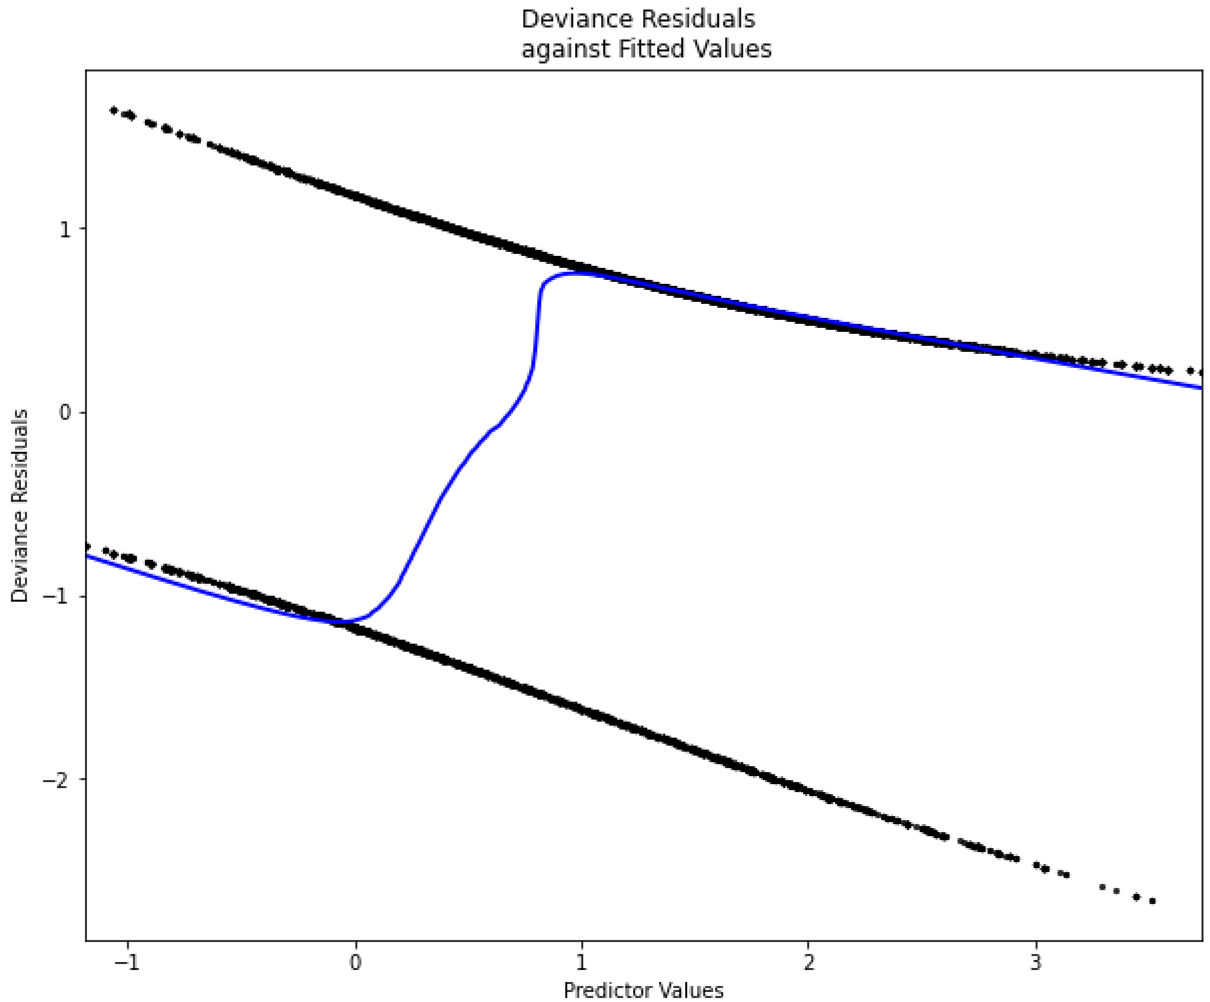
The presence of the independent variables increases or decreases the log odds of the presence of the dependent variable based on the sign of the parameter coefficients. The government regulations of school closures, travel restrictions, state of emergency declarations, wage support, tax credits, and interest rate lowering decreased the log odds of the presence of virus cases.

Goodness-of-fit tests determine whether the predicted probabilities deviate from the observed probabilities. Deviance is the difference of likelihoods between the fitted model and the residuals. 0 predicted residuals are negative and 1 predicted residuals are positive. μ̂i are the fitted values and yi are the observed values.

$$DevianceResiduals = \sum_i^N \sqrt{2[yi * log(y_i/\hat{\mu}_i) + (n_i - y_i) * log(n_i - y_i/n_i - \hat{\mu}_i)]}$$

In [33]:

```
fig, ax = plt.subplots(1, figsize=(10, 8))
sns.regplot(model.fittedvalues, model.resid_dev, ax= ax,
            color="black", scatter_kws={"s": 5},
            line_kws={"color":"b", "alpha":1, "lw":2}, lowess=True)
plt.title("Deviance Residuals \n against Fitted Values")
plt.xlabel("Predictor Values")
plt.ylabel("Deviance Residuals")
plt.show()
```



$$PearsonResiduals = \sum_i^N \frac{y_i - \hat{\mu}_i}{\sqrt{\hat{\mu}_i(n_i - \hat{\mu}_i)/n_i}}$$

In [34]:
```
fig, ax = plt.subplots(1, figsize=(10, 8))
sns.regplot(model.fittedvalues, model.resid_pearson, ax= ax,

Pearson's chi-squared test is a goodness-of-fit test that determines whether categorical observed values, O, are consistent with their coresponding expected values, E.

$$\chi 2 = \sum_{i}^{N} \frac{(O_i - E_i)^2}{E_i}$$

$$E(x) = \sum_{i}^{N} x_i * p(x_i)$$

In [43]:
```
stat, p = chisquare(model.resid_pearson)#Null Hypothesis: no significant difference between the observed and the expected values
print('Stat:', stat, 'P-value:', p)
alpha=.05
if p>alpha:
    print('Don\'t reject null of no significant difference between the observed and the expected values.')
else:
    print('Reject null of no significant difference between the observed and the expected values.')
```

The log loss, a cost function, is the cross entropy between the distribution of the true labels and the predictions. Entropy measures unpredictability and cross entropy incorporates the entropy of the predicted distribution with of the true distribution. The log loss multiplies -1 by the log likelihood to identify that lower scores are better, devides the result by the sample size, and reults in the mean loss. As the loss approaches 0, the probability of correct classification increases.

$$NegativeLogLoss = -\frac{1}{N}\sum_i^N y_i * log(\sigma(\theta^T * x_i) + (1 - y_i) * log(1 - \sigma(\theta^T * x_i))$$

Conclusion

The logit model suggests that the government regulations of school closures, travel restrictions, state of emergency declarations, wage support, tax credits, and interest rate lowering decreased the log odds of the presence of virus cases. Government regulations such as disallowing public gatherings and mandating wearing masks did not decrease the log odds of the presence of virus cases. The virus travels in sneezed or coughed droplets of mucus or saliva, is airborne for a few moments, and then lands on a surface. Instead of wearing masks and preventing gatherings, carrying a handkerchiefs in which people could sneeze or cough and sanitizing areas were people gather would be sufficient in preventing the spread of SARS-CoV-2.
